

Electronic Properties of Rocksalt Copper Monoxide

PAUL MICHAEL GRANT, W2AGZ Technologies — Rocksalt copper monoxide, although not yet synthetically realized in bulk form, can be studied computationally as a proxy for the family of layered HTSC copper oxides. We report results for a series of tetragonal CuO rocksalt structures with c/a lattice parameter ratios ranging from 1.0 to 1.5, employing the plane-wave pseudopotential method with exchange/correlation LDA+U. As expected, we obtain a metallic state for $U = 0$ at all values of c/a given that the nominal valence electron configuration for Cu in copper monoxides is $3d^9$ yielding a partially occupied conduction band. However, completely unexpected was our finding similar metallic properties in rocksalt CuO for all physically plausible values of U (up to 10 eV) and c/a between 1.0 to approximately 1.2. Only for $c/a > 1.2$ do our calculations reveal the opening of a Mott-Hubbard charge-transfer gap. We interpret our results¹ as supporting the original motivations of Bednorz and Mueller that high temperature superconductivity in the layered copper oxide perovskites may begin with their tendency to exhibit Jahn-Teller strong electron-phonon coupling².
